When migrating between different infrastructures (i.e. from on-prem to cloud, or from one cloud provider to another cloud provider), select the source location as *Generic*, and then select the target cloud region of choice.

When migrating between different regions of the same cloud provider, you may select the source cloud region accordingly.
You may also set the same region as both source and target when migrating workloads between zones in the same region, or for cloning/staging/dev-test purposes.
